Abstract

Gather a list of data sets, type of datasets, and hyperparameters by running an expanded list of datasets. This information will be embedded in a database management system, to be incorporated into a website where it is easy to be searched and used by the public.

The hyperparameter database is created by running millions of hyperparameter values, over thousands of public datasets and calculating the individual conditional expectation of every hyperparameter on the quality of a model.

Generate models using H2O software to find the best hyperparameters and create a conceptual model and store all the data into a physical database.

Objective:

To create Hyperparameter Database by running several hyperparameter values on several datasets and to calculate the individual conditional expectations on every hyperparameter on quality of model

Project Requirement:

Unique datasets are to be picked from different data sources like Kaggle Datasets, UCI machine learning repository, Amazon Datasets, Google Datasets, Computer Vision Datasets etc. Identify the type of dataset chosen, ie Regression, Classification, Clustering etc. Perform data cleaning and data pre-processing. Create conceptual and ER diagrams. Perform database normalization and perform analytics on the database created to get the best values for the hyperparameters.

Problems to be addressed:

Most of the algorithms that improve metrics, degrades the quality of search results. Hyperparameter optimization is performed to overcome the issues addressed by those algorithms and build models for visualizing and teaching statistical concepts.

Potential pitfalls & challenge:

Different optimization methods will have different setup steps, time requirements, and performance outcomes. Hence, methods like algorithmic optimization will help in achieving better performance.

Data source

Data is derived from Kaggle Datasets. We have chosen considered dataset of Travel Insurance.

A third-party TRAVEL INSURANCE servicing company that is based in Singapore.

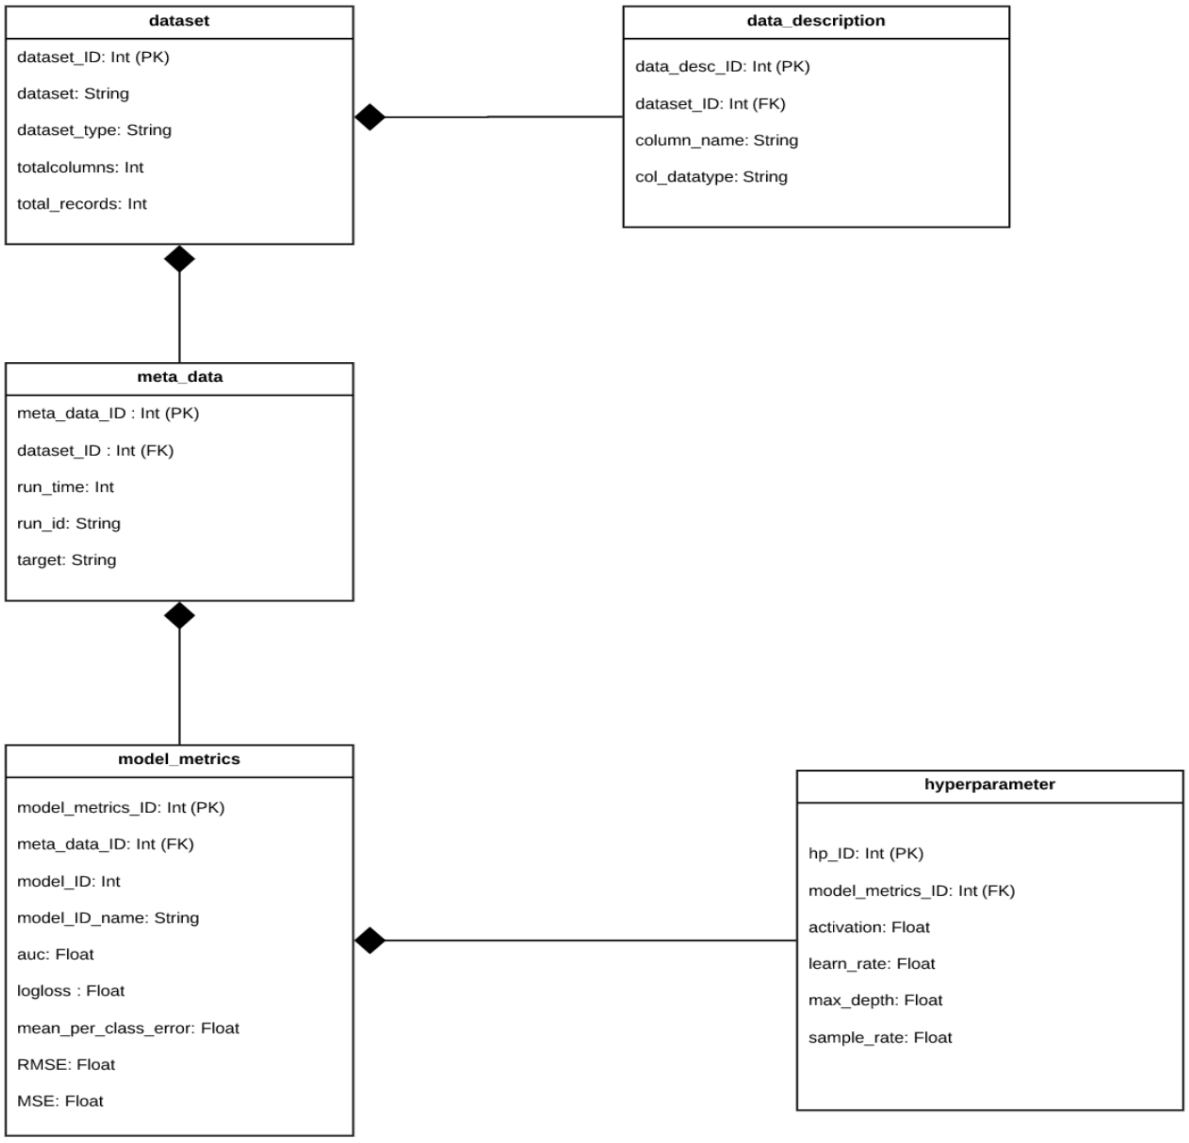
The attributes:

- Target: Claim Status
- Name of agency
- Type of travel insurance agencies
- Distribution channel of travel insurance agencies
- Name of the travel insurance products
- Duration of travel
- Destination of travel
- Amount of sales of travel insurance policies
- Commission received for travel insurance agency
- Gender of insured
- Age of insured

Conceptual Schema

A conceptual data model identifies the highest-level relationships between the different entities.

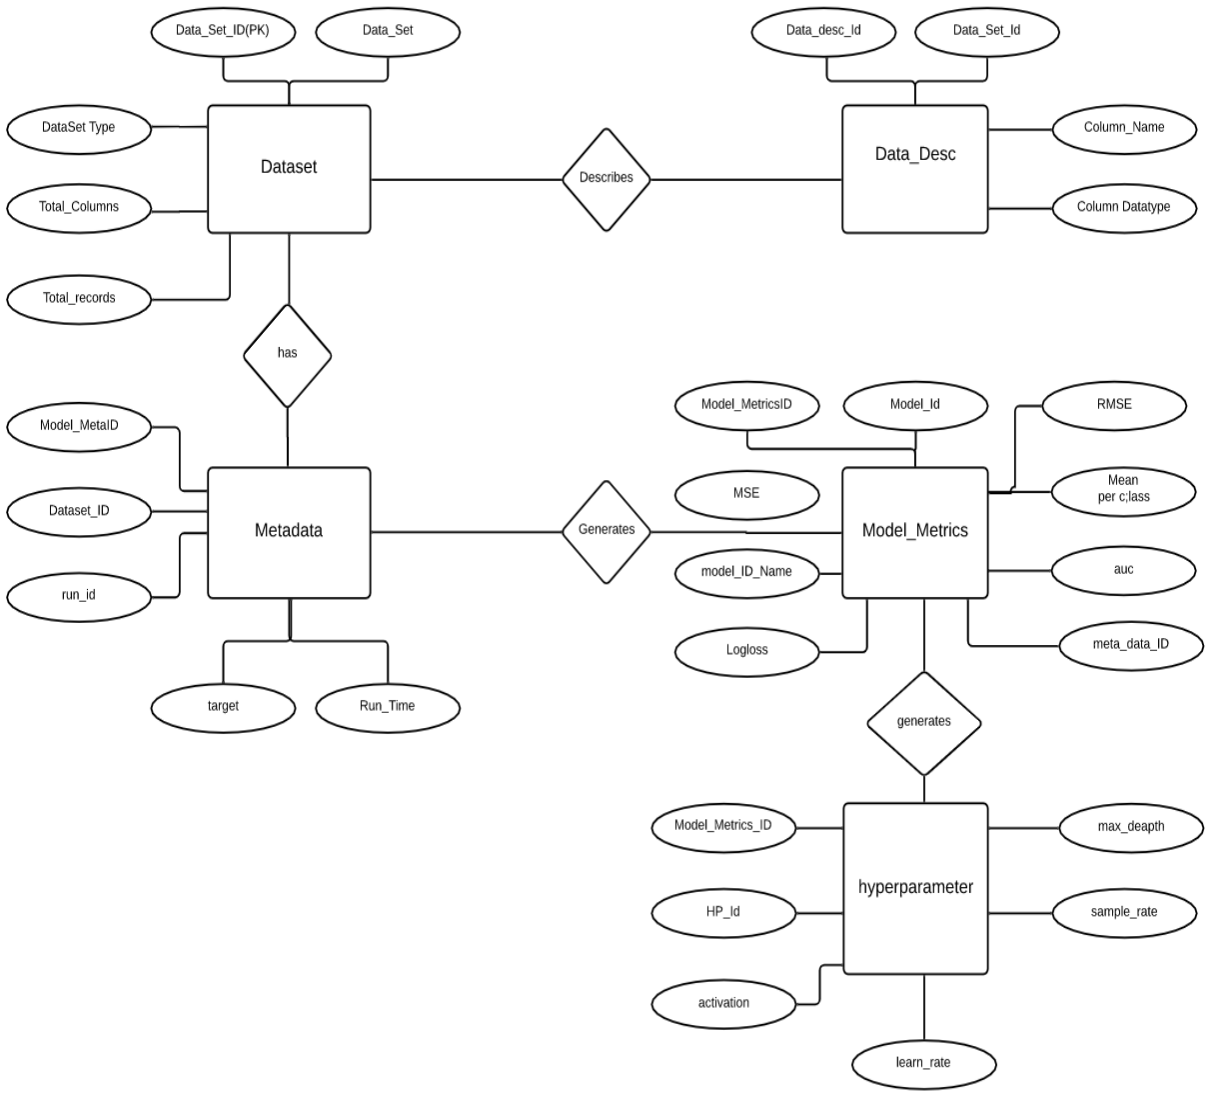
- dataset_ID is the primary key of dataset table.
- data_desc_ID is the primary key and dataset_ID is the foreign key of data_description table.
- meta_data_ID is the primary key and dataset_ID is the foreign key of meta_data table.
- model_metrics_ID is the primary key and meta_data_ID is the foreign key of model_metrics table.
- hp_ID is the primary key and model_metrics_ID is the foreign key of hyperparameter table.



ER Diagram

An entity relationship diagram shows the relationships of entity sets stored in a database. An entity is an object, a component of data. An entity set is a collection of similar entities. These entities have attributes that define its properties.

Entity dataset describes the entity data_description and has the entity meta_data. Entity meta_data generates entity model_metrics. Entity model_metrics generates hyperparameter entity.



Normalization

According to 1NF,

1. There are no repeating groups
2. Maintained atomic data values of hyperparameter table is further split into hyperparameter_default and hyperparameter_actual columns
3. Each field of the table has unique name
4. Each table has primary key

According to 2NF,

1. All tables satisfy 1NF
2. All non-key attributes are dependent on all parts of primary key. Thus, no partial dependencies
3. There are no calculated data
4. Each field of the table has unique name
5. Each table has primary key

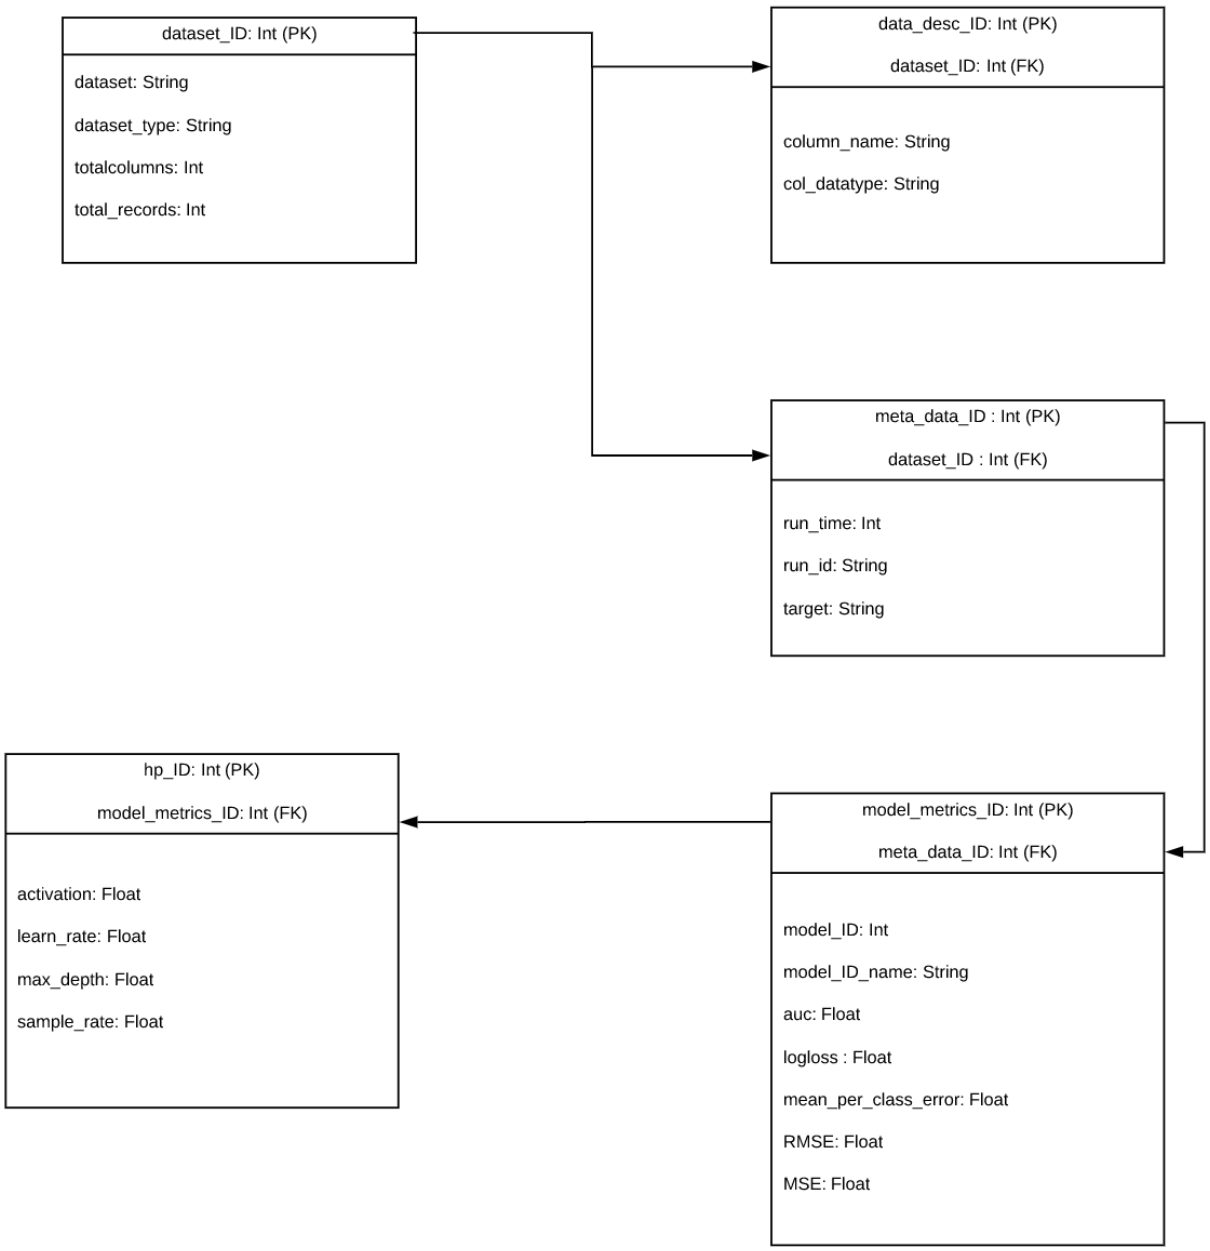
According to 3NF,

1. All tables satisfy 2NF
2. All non-key attributes are not dependent on other non-key attributes. Thus, no transitive relationship
3. Each field of the table has unique name
4. Each table has primary key

Physical Model

Physical data model represents how the model will be built in the database. A physical database model shows all table structures, including column name, column data type, column constraints, primary key, foreign key, and relationships between tables.

All the entities from ER diagram is converted to tables. All the attributes are converted into columns of respective tables. All the relationships are converted into foreign keys.



Use Cases

1. Number of ‘run time’ for dataset ‘Travel Insurance’
2. Number of models for run time ‘1000’
3. Return the actual value of learn_rate for model ID 1
4. What are the metric values of the learn_rate of model 1 of run time 1000
5. Which run time has the highest RMSE value
6. Which run time has the least logloss value
7. Total number of models generated for all the runs
8. Auc value for model 3 of run time 1500
9. Display the number of models for each run times
10. Which Run has the best model

Functions

Conclusion

Hyperparameter database is built by running several hyperparameter values on Travel Insurance dataset. Data fetched from the dataset is structured into different tables analyzing the relationships between the values.

Using H20 software, for five run times (500, 1000, 1500, 2000, 2500), respective models and its metrics values are generated. Metrics indicate the absolute fit of the model to actual data. Smaller the metrics values, closer we are to finding the line of best fit. Thus, models generated their own set of hyperparameters. Hence, model architecture is defined for storing the hyperparameter values in the database.
